ICO Guidelines for Diabetic Eye Care
ICO Guidelines for Diabetic Eye Care

The International Council of Ophthalmology (ICO) developed the ICO Guidelines for Diabetic Eye Care to serve a supportive and educational role for ophthalmologists and eye care providers worldwide. They are intended to improve the quality of eye care for patients around the world.

The Guidelines address the needs and requirements for the following levels of service:

- Low-resource or resource-poor settings: Essential or core service for screening and management of DR
- Intermediate-resource settings: Mid-Level service
- Resource-rich settings: Advanced or state-of-the-art screening and management of DR

The Guidelines are designed to inform ophthalmologists about the requirements for the screening and detection of diabetic retinopathy, and the appropriate assessment and management of patients with diabetic retinopathy. The Guidelines also demonstrate the need for ophthalmologists to work with primary care providers and appropriate specialists such as endocrinologists.

With diabetes and diabetic retinopathy a rapidly increasing problem worldwide, it is vital to ensure that ophthalmologists and eye care providers are adequately prepared.

The ICO believes an ethical approach is indispensable, as it is the first step toward quality clinical practices. Download the ICO Code of Ethics at: [www.icoph.org/downloads/icoethicalcode.pdf](http://www.icoph.org/downloads/icoethicalcode.pdf) (PDF – 198 KB).

The Guidelines are designed to be a working document and will be updated on an ongoing basis. They were first released in December 2013. This document was updated and reprinted in February 2014.

The ICO hopes these Guidelines are easy to read, translate, and adapt for local use. The ICO welcomes any feedback, comments, or suggestions.

Please email us at: info@icoph.org.

I. Introduction

Diabetes mellitus (DM) is a global epidemic with significant morbidity. Diabetic retinopathy (DR) is the specific microvascular complication of DM and affects 1 in 3 persons with DM. DR remains a leading cause of vision loss in working adult populations. Patients with severe levels of DR are reported to have poorer quality of life and reduced levels of physical, emotional, and social well-being, and they utilize more health care resources.

Epidemiological studies and clinical trials have shown that optimal control of blood glucose, blood pressure, and blood lipids can reduce the risk of developing retinopathy and slow its progression. Timely treatment with laser photocoagulation, and increasingly, the appropriate use of intraocular administration of vascular endothelial growth factor (VEGF) inhibitors can prevent visual loss in vision-threatening retinopathy, particularly diabetic macular edema (DME). Since visual loss may not be present in the earlier stages of retinopathy, regular screening of persons with diabetes is essential to enable early intervention.

Epidemiology of Diabetic Retinopathy

In many countries, DR is the most frequent cause of preventable blindness in working-aged adults. In the United States, an estimated 40% (8% for vision-threatening retinopathy) of persons with type 2 diabetes and 86% (42% for vision-threatening retinopathy) of persons with type 1 diabetes have DR. High prevalence estimates have also been reported in other countries. Despite concern about a potential diabetes epidemic in Asia, epidemiologic data for DR in Asian countries is relatively limited. In Latin America, 40% of diabetic patients had some DR and 17% required treatment. Few studies of DR have been conducted in Africa.

DR develops with time and is associated with poor control of blood sugar, blood pressure, and blood lipids. The longer someone has had DM, and the poorer their control, the higher their risk of developing DR. Good control reduces the annual incidence of developing DR and extends life. However, good control does not necessarily reduce the lifetime risk of developing DR, so everyone with DM is at risk.

The overall prevalence of DR in a community is also influenced by the number of people diagnosed with early DM:

- In resource-rich settings with good health care systems, more people with early DM will have been diagnosed. The prevalence of DR in people with newly diagnosed DM will be low, resulting in a lower overall prevalence of DR.
- In resource-poor settings with less advanced health care systems, fewer people with early DM will have been diagnosed. People may be diagnosed with diabetes only when symptomatic or complications have occurred. Thus, the prevalence of DR in people with newly diagnosed DM will be high, resulting in a somewhat higher overall prevalence of DR.

In general, meta-analysis of large scale studies show that approximately one third of those with DM will have DR, and approximately one third of those (or 10% of persons with DM) will have vision-threatening DR that requires treatment.

Classification of Diabetic Retinopathy

The classic retinal microvascular signs of DR include microaneurysms, hemorrhages, hard exudates (lipid deposits), cotton-wool spots (ischemic retina related to accumulations of axoplasmic debris within adjacent bundles of ganglion cell axons), venous dilation and beading, and intraretinal microvascular abnormalities (i.e., dilated pre-existing capillaries). (Annex Figures). These signs can be classified into two phases of DR.

Nonproliferative Diabetic Retinopathy

Nonproliferative DR is the early stage of DR. Recognition of nonproliferative retinopathy allows a prediction of risk of progression, visual loss, and determination of a review interval. Annex Table 1 shows the signs of nonproliferative DR.

Proliferative Diabetic Retinopathy

Proliferative diabetic retinopathy (PDR) is a severe stage of DR and represents an angiogenic response of the retina to extensive ischemia and capillary closure. Neovascularization has been divided into 2 groups: new vessels on the disc (NVD) and new vessels elsewhere (NVE). Typically NVE grow at the interface of perfused and nonperfused retina. Annex Table 2 shows the signs of PDR.

The stages of DR, from nonproliferative to proliferative DR, can be classified using the simple international classification of DR scale shown in Table 1. DME is an important complication that is assessed separately from the stages of retinopathy, as it can be associated with any of the DR stages and can run an independent course.

Diabetic Macular Edema

It is important to assess the presence and severity of diabetic macular edema (DME) separately from stages of DR.
The stages of DR can be classified using the International Classification of DR Scale shown in Table 1. A simplified grading based on this with referral decision can be used in low-resource settings (Table 2). It is important to remember that early DME may be first detected by a reduction in visual acuity. An online self-directed course on the grading of diabetic retinopathy is available at: [drgrading.iehu.unimelb.edu.au](http://drgrading.iehu.unimelb.edu.au).

### Table 1: International Classification of Diabetic Retinopathy and Diabetic Macular Edema and Referral Recommendations

<table>
<thead>
<tr>
<th>Diabetic Retinopathy</th>
<th>Findings Observable on Dilated Ophthalmoscopy</th>
<th>Referral</th>
</tr>
</thead>
<tbody>
<tr>
<td>No apparent retinopathy</td>
<td>No abnormalities</td>
<td>Review in 1–2 years</td>
</tr>
<tr>
<td>Mild nonproliferative DR</td>
<td>Microaneurysms only</td>
<td>Review in 1–2 years</td>
</tr>
<tr>
<td>Moderate nonproliferative diabetic retinopathy</td>
<td>More than just microaneurysms, but less than severe nonproliferative DR</td>
<td>Review in 6 months -1 year; or refer to ophthalmologist</td>
</tr>
<tr>
<td>Severe nonproliferative DR</td>
<td>Any of the following:</td>
<td>Refer to ophthalmologist</td>
</tr>
<tr>
<td></td>
<td>• Intraretinal hemorrhages (≥20 in each quadrant);</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Definite venous beading (in 2 quadrants);</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Intraretinal microvascular abnormalities (in 1 quadrant);</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• and no signs of proliferative retinopathy</td>
<td></td>
</tr>
<tr>
<td>Proliferative DR</td>
<td>Severe nonproliferative DR and 1 or more of the following:</td>
<td>Refer to ophthalmologist</td>
</tr>
<tr>
<td></td>
<td>• Neovascularization</td>

<table>
<thead>
<tr>
<th>Diabetic Macular Edema</th>
<th>Findings Observable on Dilated Ophthalmoscopy*</th>
<th>Referral</th>
</tr>
</thead>
<tbody>
<tr>
<td>DME absent</td>
<td>No retinal thickening or hard exudates in posterior pole</td>
<td>Review in 1-2 years</td>
</tr>
<tr>
<td>DME present</td>
<td>Retinal thickening or hard exudates in posterior pole</td>
<td>Refer to ophthalmologist</td>
</tr>
<tr>
<td>Mild DME</td>
<td>Retinal thickening or hard exudates in posterior pole but outside the central subfield of the macula (diameter 1000 μm)</td>
<td></td>
</tr>
<tr>
<td>Moderate DME</td>
<td>Retinal thickening or hard exudates within the central subfield of the macula but not involving the center point</td>
<td></td>
</tr>
<tr>
<td>Severe DME</td>
<td>Retinal thickening or hard exudates involving the center of the macula</td>
<td></td>
</tr>
</tbody>
</table>

*Hard exudates are a sign of current or previous macular edema. DME is defined as retinal thickening, and this requires a three-dimensional assessment that is best performed by a dilated examination using slit-lamp biomicroscopy and/or stereo fundus photography.

II. Screening Guidelines

Screening Guidelines

Screening for DR is an important aspect of DM management worldwide. Even if an adequate number of ophthalmologists are available, using ophthalmologists or retinal subspecialists to screen every person with DM is an inefficient use of resources.

A screening exam could include a complete ophthalmic examination with refracted visual acuity and state-of-the-art retinal imaging. However, in a low-resource setting, the minimum examination components to assure appropriate referral should include a screening visual acuity exam and retinal examination adequate for DR classification. Vision should be tested prior to pupil dilation. Annex Figure 1 shows an example of the screening process for DR.

The screening vision exam should be completed by trained personnel in any of the following ways, depending on resources:

- Refracted visual acuity examination using a 3- or 4-meter visual acuity lane and a high contrast visual acuity chart.
- Presenting visual acuity examination using a near or distance eye chart and a pin-hole option if visual acuity is reduced.
- Presenting visual acuity examination using a 6/12 (20/40) equivalent handheld chart consisting of at least 5 standard letters or symbols and a pin-hole option if visual acuity is reduced.

A retinal examination may be accomplished in the following ways:

- Direct or indirect ophthalmoscopy or slit-lamp biomicroscopic examination of the retina.
- Retinal (fundus) photography (including any of the following: widefield to 30°; mono- or stereo-; dilated or undilated). This could be done with or without accompanying optical coherence tomography (OCT) scanning. This could also include telemedicine approaches. (Annex Table 3)
- For the retinal examination, a medical degree may not be necessary, but the examiner must be well trained to perform ophthalmoscopy or retinal photography and be able to assess the severity of DR.

Using adequate information from the visual acuity and retinal examinations, one can decide on an appropriate management plan, as outlined in Table 2. The plan may be modified based on individual patient requirements.

Patients with less than adequate retinal assessment should be referred to an ophthalmologist unless it is obvious that there is no DR, or at most, only mild nonproliferative DR (i.e., microaneurysms only). In addition, persons with unexplained visual-acuity loss should be referred.

As part of a screening exam, persons with diabetes should be asked about their diabetes control, including blood
glucose, blood pressure, and serum lipids. In addition, women should be asked if they are or could be pregnant. Inadequate control and pregnancy may require further appropriate medical intervention.

Referral Guidelines
Minimum referral guidelines are as follows:

- Visual acuity below 6/12 (20/40) or symptomatic vision complaints
- If DR can be classified according to the International Classification of DR or a Simplified scheme, they should be referred accordingly (Table 1 and 2)
- If retinal exam or retinal imaging is available but only a less detailed classification of DR is possible:
  - No retinopathy or only a few small red spots: return for screening exam in 1–2 years
  - Dot or blot hemorrhages or possible neovascularization: refer to ophthalmologist
  - White spots in the retina: refer to ophthalmologist
- If visual acuity or retinal examination cannot be obtained at the screening examination: refer to ophthalmologist
- Patients who have had laser treatment should also be referred for ophthalmic review

III. Detailed Ophthalmic Assessment of Diabetic Retinopathy

1. Initial Patient Assessment
Detailed patient assessment should include a complete ophthalmic examination, including visual acuity and the identification and grading of severity of DR and presence of DME for each eye. The patient assessment should also include the taking of a patient history focused on diabetes and its modifiers.

a. Patient History (Key Elements)
- Duration of diabetes
- Past glycemic control (hemoglobin A1c)
- Medications (especially insulin oral hypoglycemics, antihypertensives, and lipid-lowering drugs)
- Systemic history (e.g., renal disease, systemic hypertension, serum lipid levels, pregnancy)
- Ocular history

b. Initial Physical Exam (Key Elements)
- Visual acuity
- Measurement of intraocular pressure (IOP)
- Gonioscopy when indicated (e.g., when neovascularization of the iris is seen or in eyes with increased IOP)
- Slit-lamp biomicroscopy
- Fundus examination

c. Fundus Examination Assessment Methods
Currently, the two most sensitive methods for detecting DR are retinal photography and slit-lamp biomicroscopy through dilated pupils. Both depend on interpretation by trained eye health professionals. Other methods are listed in Annex Table 2.

Fundus photography has the advantage of creating a permanent record, and for that reason, it is the preferred method for retinopathy assessment. However, well-trained observers can identify DR without photography and there are many situations in which that would be the examination of choice.

The use of all instruments requires training and competence but more skill is needed for indirect ophthalmoscopy and slit-lamp biomicroscopy than for fundus photography. Newer, semi-automatic nonmydriatic fundus cameras can be very easy to use. Media opacities will lead to image/view degradation and all photographs/images must be reviewed by trained personnel.
2. Follow-up Examination of Patients with Diabetic Retinopathy

In general, the follow-up history and examination should be similar to the initial examination. The assessment of visual symptoms, visual acuity, measurement of IOP, and fundus examination are essential.

a. Follow-up History
   - Visual symptoms
   - Glycemic status (hemoglobin A1c)
   - Systemic status (e.g., pregnancy, blood pressure, serum lipid levels, renal status)

b. Follow-up Physical Exam
   - Visual acuity
   - Measurement of IOP
   - Gonioscopy when indicated
   - Slit-lamp biomicroscopy
   - Fundus examination

c. Ancillary Tests
   - Fluorescein angiography is not needed to diagnose DR, proliferative DR or DME, all of which are diagnosed by means of the clinical exam.
   - Fluorescein angiography can be used as a guide for treating DME and as a means of evaluating the cause(s) of unexplained decreased visual acuity. Fluorescein angiography can also identify macular capillary nonperfusion or sources of capillary leakage resulting in DME as possible explanations for visual loss.
   - OCT is the most sensitive method to identify sites and severity of DME.

d. Patient Education
   - Discuss results or exam and implications.
   - Encourage patients with DM but without DR to have annual screening eye exams.
   - Inform patients that effective treatment for DR depends on timely intervention, despite good vision and no ocular symptoms.
   - Educate patients about the importance of maintaining near-normal glucose levels, near-normal blood pressure and to control serum lipid levels.
   - Communicate with the general physician (e.g., family physician, internist, or endocrinologist) regarding eye findings.
   - Provide patients whose conditions fail to respond to surgery and for whom treatment is unavailable with proper professional support (i.e., offer referrals for counseling, rehabilitative, or social services as appropriate).
   - Refer patients with reduced visual function for vision rehabilitation and social services.
Table 3. Follow-up Schedule and Management for Diabetic Retinopathy Severity According to Resources Available

For all patients regardless of DR severity, optimize medical treatment for glycemic control, hypertension, and dyslipidemia.

IV. Treatment of Diabetic Retinopathy

Panretinal laser photocoagulation surgery should be performed in patients with proliferative DR. There are benefits of early panretinal photocoagulation at the severe nonproliferative DR stage for patients with type 2 diabetes. Other factors, such as poor compliance with follow up, impending cataract extraction or pregnancy, and status of fellow eye will help in determining the timing of the panretinal photocoagulation.

1. Panretinal Photocoagulation (PRP)
   a. Pretreatment Discussion with Patients
      - Patients usually need numerous follow-up visits and may require supplementary laser treatment.
      - PRP reduces the risk of visual loss and blindness.
      - Although laser treatment is effective, some patients may still develop vitreous hemorrhage. The hemorrhage is caused by the diabetes and not by the laser; it may mean the patient needs more laser treatment.
      - Laser treatment often reduces peripheral and night vision; treatment may moderately reduce central vision. This short-term side effect is compensated by the significant long-term reduction in severe vision loss and blindness in laser-treated patients.
   b. Lenses for PRP
      - The three-mirror Goldmann contact lens has a central opening for treating the posterior pole, and side mirrors for treating the mid peripheral and peripheral retina. Disadvantages: small field of view, which requires continual manipulation of the lens to complete treatment. Spot size is set at 500µm.
      - Newer wide-angle contact lenses are often used. Although the image is inverted, there is a large field of view allowing for many burns with the field while easily maintaining orientation to the disc and macula. The optics of these wide-angle lenses will affect the laser spot size on the retina (Table 4). Wide-angle indirect ophthalmoscopy lenses provide an inverted image, but show a large field of view and a magnification of the spot in the retina (Table 4). Scatter treatment can be applied to a large area of retina in a single image, and it is easy to visualize the disk and the macula.

c. Technique for PRP

i. The pupil should be fully dilated and topical anesthesia is used. Retrobulbar or subtenons anesthesia to reduce pain and decrease eye motion can be employed as necessary.

ii. The most common wavelengths used are Argon green, blue green (generally avoided currently), and 532 green laser, using the slit-lamp delivery system. In case of hazy media, Krypton red or diode red laser (814 nm) can be used. Slit-lamp treatment is most commonly done through a contact lens but can also be performed using indirect ophthalmoscopy. For example, when treatment is given under general anesthesia.

iii. Typical initial settings on the Argon laser would be 500 µm spot size, a 0.1 second exposure and 250-270 mw power. The power is gradually increased until a whitish reaction is obtained on the retina. The lesions are placed 1 burn width apart. (Table 5)

iv. A total of 1600-3000 burns are placed in 1 or more sittings, carefully avoiding the macular area and any areas of tractional elevation of the retina. The burns are placed 2 to 3 disc diameters away from the center of the macula and 1 disc diameter away from the disc, usually outside the arcades and extended peripherally up to the equator and beyond.

v. Laser treatment should not be applied over major retinal veins, preretinal hemorrhages, darkly pigmented chorioretinal scars, or within 1 DD (200-300 µm) of center of macula, so as to avoid risk of hemorrhage or large scotomas.

vi. Other considerations:
   - Additional photocoagulation is needed if there is evidence of worsening of proliferative DR.
   - Add laser burns in between scars of initial treatment further peripherally and also at the posterior pole, sparing the area within 500-1500 µm from the center of the macula.
   - Favor quadrants with active new vessels or areas with intraretinal microvascular abnormalities where scars are more widely spaced and areas of severe ischemia not previously treated, such as the temporal part of the posterior pole.
   - Direct treatment of NVE in between scars is possible.
   - A subthreshold micropulse diode laser or multi-spot laser can be used.

d. Panretinal (Scatter) Photocoagulation Technique Following Diabetic Retinopathy Clinical Research Network (DRCRNet) Consensus

Panretinal (scatter) photocoagulation initially consists of 1200 to1600 burns (or the equivalent area treated with a multi-spot laser), with a spot size on the retina of approximately 500 µm given over 1 to 3 sittings and completed within eight weeks (56) days of initiation. (Table 5)

### 2. Treatment For Diabetic Macular Edema

#### a. Resource-Rich Settings

- i. Optimize medical treatment: Improve glycemic control if HbA1c > 7.5% as well as associated systemic hypertension or dyslipidemia.

- ii. Mild or moderate DME without center involvement (e.g., circinate HE ring threatening the center of the macula or when no vision loss has occurred in spite of center involvement): Consider focal laser to leaking microaneurysms. No treatment is applied to lesions closer than 300 µm from the center of the macula.

- iii. Severe DME with center involvement and associated vision loss*: intravitreal anti-VEGF treatment (e.g., with ranibizumab [Lucentis] 0.3 or 0.5mg, bevacizumab [Avastin] 1.25mg, or Aflibercept [Eylea] 2mg therapy). Consideration should be given to monthly injections followed by treatment interruption and re-initiation based on visual stability and OCT. Patients should be monitored almost monthly with OCT to consider the need for treatment. Typically, the number of injections is 8 the first year, 2 or 3 during the second year, and 1 to 2 during the third year. Persistent retinal thickening and leaking points: consider laser treatment after 24 weeks. Treatment with intravitreal triamcinolone may be considered, especially in pseudophakic eyes. (Annex Figures 3 and 4). Injections are given 4 mm behind the limbus in the inferotemporal quadrant under topical anesthesia using a sterile technique.

- iv. DME associated with proliferative DR: combined intravitreal anti-VEGF therapy and PRP should be considered.

- v. Vitreomacular traction or epiretinal membrane on OCT: pars plana vitrectomy may be indicated.

*For eyes with severe DME with center involvement and good visual acuity (20/25 or better), 3 treatment options being evaluated in an ongoing clinical trial: (1) careful follow-up with anti-VEGF treatment only for worsening DME; (2) anti-VEGF injections; or (3) laser photocoagulation with anti-VEGF, if necessary.

#### b. Intermediate or Low-Resource Settings

- i. Generally similar to above. Focal laser is preferred if intravitreal injection of anti-VEGF agents are not available. Bevacizumab (Avastin) is an appropriate alternative to raniziumab (Lucentis) or aflicercept (Eylea). Laser can be applied earlier to areas of persistent retinal thickening in eyes unresponsive to anti-VEGF treatment.
c. Laser Technique for Macular Edema
   i. Focal macular treatment includes focal laser treatment of microaneurysms and grid treatment of areas of diffuse leakage and focal nonperfusion within 2DD of center of the macula. (Table 6)
   ii. Laser parameters used are 50-100 μm spot size, 120-150 mW energy and very light gray intensity of the burn. Care is taken to demarcate and avoid the foveal avascular zone.
   iii. If DME is associated with large areas of macular ischemia, only the areas of retinal thickening are treated.

• No burns are placed within 500 μm of the disc |
| Burn size for grid treatment         | 50-100 μm                                                                                                               | 50 μm                                       |
| Burn duration for grid treatment     | 0.05 to 0.1 sec                                                                                                         | 0.05 to 0.1 sec                             |
| Burn intensity for grid treatment    | Barely visible (light gray)                                                                                             | Barely visible (light gray)                 |
| Burn Separation for Grid Treatment   | Two visible burn widths apart                                                                                           | 200 to 300 total burns evenly distributed over the treatment area outlined above (approx. two to three burn widths apart) |
| Wavelength (grid and focal Treatment) | Green to yellow wavelengths                                                                                             | Green                                       |

3. Indications for Vitrectomy
   a. Severe vitreous hemorrhage of 1–3 months duration and that does not clear spontaneously.
   b. Advanced active proliferative DR that persists despite extensive PRP.
   c. Traction macular detachment of recent onset.
   d. Combined traction-rhegmatogenous retinal detachment.
   e. Tractional macular edema or epiretinal membrane involving the macula.
V. Suggested Indicators for Evaluation of DR Programs

a. Prevalence of diabetic retinopathy related blindness and visual impairment*
b. Proportion of blindness and visual impairment due to DR*
c. Last eye examination for DR among known persons with diabetes (males/females)*
   - Never had eye examination for DR
   - 0–12 months ago
   - 13–24 months ago
   - >24 months ago
   - Could be simplified as: never/0-12 months ago/>12 months ago
d. Number of patients who were examined for DR during last year
e. Number of patients who received laser and/or anti-VEGF treatment during last year

This absolute number could be used to define ratios such as:
f. Number of patients who received laser and/or anti-VEGF treatments per million general population per year
   [equivalent to Cataract Surgical Rate (CSR)]
g. Number of patients who received laser and/or anti-VEGF treatments per number of patients with diabetes in a
given area (hospital catchment area, health district, region, country)
   - Numerator: number of laser and/or anti-VEGF treatments during the last year
   - Denominator: number of patients with diabetes (population x prevalence of DM; source: IDF Atlas)
h. Number of patients who received laser and/or anti-VEGF treatments per number of persons with vision-
threatening DR in a given area (hospital catchment area, health district, region, country)
   - Numerator: number of laser and/or anti-VEGF treatments during the last year
   - Denominator: number of patients with vision-threatening DR (population x prevalence of DM x 0.117; source: IDF Atlas)

* Data available from RAAB surveys

0.117: Estimated average prevalence of vision-threatening DR.
## ANNEXES

### Annex Table 1: Features of Diabetic Retinopathy (also see the photographs continued in the annex)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>Assessment Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microaneurysms</td>
<td>Isolated, spherical, red dots of varying size. They may reflect an abortive attempt to form a new vessel or may simply be a weakness of capillary vessel wall through loss of normal structural integrity.</td>
<td>They are easiest seen on fluorescein angiography</td>
</tr>
<tr>
<td>Dot hemorrhages</td>
<td>Dot hemorrhages cannot always be differentiated from microaneurysms as they are similar in appearance but with varying size. The term dot hemorrhage/microaneurysm (H/Ma) is often used.</td>
<td></td>
</tr>
<tr>
<td>Blot hemorrhages</td>
<td>Formed where clusters of capillaries occlude leading to formation of intraretinal blot hemorrhages.</td>
<td>The lesion can be seen to be in the outer plexiform layer on fluorescein angiography where it does not mask the overlying capillary bed unlike dot and flame hemorrhages, which lie more superficially in the retina.</td>
</tr>
<tr>
<td>Cotton wool spots</td>
<td>These represent the swollen ends of interrupted axons where build-up of axoplasmic flow occurs at the edge of the infarct.</td>
<td>These features are not exclusive to DR and do not in themselves appear to increase the risk of new vessel formation. For example, they may occur in hypertension HIV/AIDS.</td>
</tr>
</tbody>
</table>
| Intraretinal microvascular anomalies   | These are dilated capillary remnants following extensive closure of capillary network between arteriole and venule. Associated features include:  

  • venous beading (foci of venous endothelial cell proliferation that have failed to develop into new vessels),  
  • Venous reduplication (rare),  
  • Venous loops (thought to develop due to small vessel occlusion and opening of alternative circulation) and  
  • Retinal pallor and white vessels | They are easiest seen on fluorescein angiography. |
| Macular changes in nonproliferative retinopathy  
  – Macular edema  
  – Macrovascular disease | Thickening of retina takes place due to accumulation of exudative fluid from damaged outer blood-retina barrier (extracellular edema) or as a result of hypoxia, leading to fluid accumulating within individual retinal cells (intracellular edema). It may be focal or diffuse.  

Flame hemorrhage and cotton wool spot formation. May occur due to arteriolar occlusion, without capillary occlusion, which frequently affects the horizontal nerve fiber layer of the retina. | The appearance of macular edema can be appreciated on stereoscopic examination or inferred by the presence of intraretinal exudate. |
| Optic disc changes                     | Occasionally swollen optic discs may be seen (diabetic papillopathy) in diabetic patients. | In diabetic papillopathy, vision is usually not significantly impaired. |
### Annex Table 2: Features of Proliferative Diabetic Retinopathy

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>Assessment Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>New vessels at the disc (NVD)</td>
<td>New vessels at the discs usually arise from the venous circulation on the disc or within 1 disc diameter of the disc NVD.</td>
<td>In order to differentiate NVD from fine normal small blood vessels note that the latter always taper to an end and do not loop back to the disc, while NVD always loop back, may form a chaotic net within the loop, and have the top of the loop of wider diameter than the base.</td>
</tr>
<tr>
<td>New vessels elsewhere (NVE)</td>
<td>New vessels, which usually occur along the border between healthy retina and areas of capillary occlusion.</td>
<td>Not to be confused with intraretinal microvascular abnormalities, which occur within areas of capillary occlusion.</td>
</tr>
<tr>
<td>Other sites of new vessels</td>
<td>New vessel formation on the iris (NVI) is uncommon but represents potentially more advanced ischemic changes. New vessel formation on the anterior hyaloid surface occurs rarely postvitrectomy if insufficient laser has been applied to the peripheral retina.</td>
<td>It is useful to perform gonioscopy in such cases to exclude new vessels in the anterior chamber angle (NVA), which can lead to neovascular glaucoma.</td>
</tr>
<tr>
<td>Fibrous proliferation</td>
<td>In proliferative retinopathy, new vessels grow on a platform of glial cells.</td>
<td></td>
</tr>

### Annex Table 3: Available Assessment Instruments and Their Advantages and Disadvantages

<table>
<thead>
<tr>
<th>Technique</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct ophthalmoscopy</td>
<td>• Mobile • Inexpensive</td>
<td>• Requires pupil dilation • Small field • Low sensitivity: even with a trained practitioner and red free illumination, small microvascular abnormalities may be difficult to detect • Less effective than slit-lamp biomicroscopy through dilated pupils • No ability to retrospectively audit</td>
<td>• Optional for screening • Pupils must be dilated</td>
</tr>
<tr>
<td>Indirect ophthalmoscopy</td>
<td>• Mobile • Large field • Relatively inexpensive</td>
<td>• Requires pupil dilation • Even with a trained practitioner and red free illumination, small microvascular abnormalities may be difficult to detect • Less effective than slit-lamp biomicroscopy through dilated pupils • No ability to retrospectively audit</td>
<td>• Optional for screening • Pupils must be dilated</td>
</tr>
<tr>
<td>Slit-lamp biomicroscopy</td>
<td>• Large field</td>
<td>• Requires pupil dilation • Immobile • Requires special lenses • No ability to retrospectively audit</td>
<td>• Required for ophthalmic examination</td>
</tr>
<tr>
<td>Nonmydriatic retinal photography</td>
<td>• Large field • Can be used by non-medically trained staff • No dilation required in 80-90% of cases • Some are portable - can be transported to the community in mobile units • Can be linked to computers and images can be stored for the long term • Allows objective comparison of the same person, or between different groups of people, examined at different times or by different professionals • Can be used as a patient education tool, giving immediacy and personal relevance • Readily recalled for evaluation of screener performance and audit of grading • Relatively expensive • A dark space is required for maximum pupil dilation • Auditable</td>
<td>• Recommended for screening</td>
<td></td>
</tr>
</tbody>

<table>
<thead>
<tr>
<th>Technique</th>
<th>Advantages</th>
<th>Disadvantages</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nonmydriatic retinal photography used with mydriasis</td>
<td>• As above except pupils are dilated for better quality photos</td>
<td>• As above</td>
<td>Optional</td>
</tr>
<tr>
<td>Mydriatic retinal photography (conventional fundus camera)</td>
<td>• Large field</td>
<td>• Requires pupil dilation</td>
<td>Desirable in ophthalmic center</td>
</tr>
<tr>
<td>Fluorescein angiography</td>
<td>• Only method of assessing capillary circulation</td>
<td>• Invasive and needs general health status assessment</td>
<td>Desirable in ophthalmic center</td>
</tr>
<tr>
<td>OCT</td>
<td>• One of the best ways to assess macular edema (retinal thickening and intraretinal edema)</td>
<td>• Expensive</td>
<td>Desirable in ophthalmic center</td>
</tr>
<tr>
<td>Fundus autofluorescence</td>
<td>• A form of functional imaging, giving insights into the metabolic activity of the retinal pigment epithelium.</td>
<td>• Role not clearly understood</td>
<td>Optional high-resource settings</td>
</tr>
</tbody>
</table>

**Equipment**

Core/essential: for screening, initial assessment, and follow up:
- Nonmydriatic retinal (fundus) photography (recommended for screening).
- Indirect ophthalmoscopy (optional for screening, panoramic view, low magnification). Pupils must be dilated.
- Noncontact biconvex indirect lenses used with the slit lamp (90 D for screening, 78 D for more magnification).
- Direct ophthalmoscopy (optional for screening). Pupils must be dilated.
- Three-mirror contact lens used with slit lamp for stereoscopic and high-resolution images of the macula (evaluation of macular edema). Pupils must be dilated.
- Slit-lamp biomicroscope.
- Laser equipment: Currently, the most used lasers are (1) The green laser 532 nm, frequency-doubled Nd:YAG or 514 nm argon laser. The 810 nm infrared laser, or diode laser – this causes deeper burns with a higher rate of patient discomfort, but tend to be cheaper, is effective, and requires less maintenance.

Desirable in reference centers:
- OCT
- Fluorescein angiography
- Mydriatic retinal photography (large field conventional fundus camera)
- Green lasers are the most used, but the pattern-laser method, with a predetermined multispot treatment cascade and the 577 nm yellow laser can be used in selected cases

**IAPB Standard List of Equipment**

The online version of the International Agency for the Prevention of Blindness (IAPB) Standard List provides information for eye health providers on a carefully evaluated range of eye care technologies, supplies, and training resources suitable for use in settings with limited resources.

For more information and to get access, please register and log on at IAPB.standardlist.org.

Only registered users have access to the IAPB Standard List catalogue. Please be aware the registration process may take a few days for approvals to be granted.
Diabetes History; Medical History; Current Medication; Biochemical Parameters

Uncorrected Visual Acuity VA with current Spectacles

Ophthalmoscopy or Fundus Photography

VA > 20/40

VA < 20/40

Routine re-examination

Non-urgent Referral for refraction and assessment

Urgent Referral

*Need to optimize medical treatment; glycemic control, hypertension and lipids.

NPDR = non-proliferative diabetic retinopathy
PDR = proliferative diabetic retinopathy
DME = diabetic macular edema
VA = visual acuity

Figure 1: Screening for Diabetic Retinopathy

Figure 2: Treatment decision tree of DME based on Center-Involvement and Vision

DME

Assessment: Clinical and OCT
Center involvement?

NO

VA 20/40 or worse (indicative of DME)?

NO

Focal Laser treatment

YES

Treatment failure

Anti-VEGF treatment

DME = diabetic macular edema
VA = visual acuity
Anti-VEGF treatment for DME

Initial treatment with injections given 3 monthly

Figure 3: Anti-VEGF treatment decision tree based on the RESTORE study treatment and re-treatment schedule

Stable VA achieved\(^a\)

Suspend treatment; return for monthly follow-up

Worsening of DME\(^b\)

Reinitiate monthly injection

Continue with 1 injection per month

a. VA was considered to have stabilised if there was no (further) improvement in best corrected visual acuity (BCVA) at the last 2 consecutive visits, or if a BCVA letter score of 6/6 was observed at the last 2 consecutive visits.

b. Decrease in BCVA and confirmed by OCT and/or other anatomical and clinical assessments.

VEGF=vascular endothelial growth factor
DME=diabetic macular edema
VA=visual acuity
Anti-VEGF treatment for DME

Assessment 1 month\(^a\) after initial injections\(^b\)

- **DME improving\(^c\)**
  - Re-inject and return in 1 month
  - Double follow-up interval up to 4 months\(^d\)

- **DME worsens or recurs**
  - No injection\(^e\) and return in 1 month
  - No

\(\text{VEGF}=\text{vascular endothelial growth factor}
\text{DME}=\text{diabetic macular edema}
\text{VA}=\text{visual acuity}\)

---

\(\text{a. In the DRCR.net study, 4-week, not 1-month, intervals were used.}\)

\(\text{b. The DRCR.net study required 4 injections of intravitreal ranibizumab every 4 weeks initially; it is not known whether a different number of injections initially would have worked as well. DRCR.net also required 2 additional injections at months 5 and 6 if edema persisted and success had not been met, even in the absence of improvement.}\)

\(\text{c. Relevant details from the DRCR.net study: 1) DRCR.net “improvement” on Zeiss Stratus OCT >10% decrease in central subfield thickness; 2) Even if no longer improving on OCT, injections continued if VA “improvement” (unless 6/6 or better); 3) VA improvement defined as 5 or more letter increase on Electronic ETDRS Visual Acuity Test.}\)

\(\text{d. In the DRCR.net study, if focal/grid laser was deferred at baseline, it was added at or after 24 weeks if edema still present and OCT central subfield and vision no longer improving.}\)

\(\text{e. In the DRCR.net study, all patients received at least 4 injections 4 weeks apart. The decision to re-inject was at investigator discretion, starting at 16 weeks for “success”, defined as VA better than 6/6 or OCT central subfield <250 μm. Starting at 24 weeks, re-injection was also at investigator discretion if no improvement in OCT central subfield or vision.}\)

\(\text{f. The DRCR.net study continued follow-up every 4 weeks through the 52-week visit and did not permit extension of follow-up until after the 52-week visit. If injection was withheld due to no improvement or success at 3 consecutive visits following the week 52 visit, follow-up interval was doubled to 8 weeks and then again to 16 weeks if still no change.}\)

Guidelines for Screening, Assessing, and Treating Diabetic Eye Disease

To create the ICO Guidelines for Diabetic Eye Care, the ICO collected guidelines from around the world for screening, assessing, and treating diabetic eye disease. This is part of a new initiative to reduce worldwide vision loss related to diabetes.

In addition to creating a consensus on technical guidelines, as encompassed in the ICO Guidelines for Diabetic Eye Care, these resources will also be used to focus on:

- Incorporating the critical competencies into ICO curricula and stimulating improved training and continuing professional development to meet public needs.
- Developing a framework for evaluation of public health approaches and stimulating development, strengthening, and monitoring of relevant health systems.

Please send questions, comments, or additional resources to: info@icoph.org.

About the ICO

The ICO is composed of 120 national and subspecialty Member societies from around the globe. ICO Member societies are part of an international ophthalmic community working together to preserve and restore vision. Learn more at: www.icoph.org.

Printing Credit

The ICO Guidelines for Diabetic Eye Care were printed for the World Ophthalmology Congress® of the ICO by the Singapore Eye Research Institute (SERI), Singapore National Eye Center. Learn more about SERI at: www.seri.com.sg.

Photo Credit

The photos that appear in the ICO Guidelines for Diabetic Eye Care were provided by:
